

## Supporting Information:

### On the causal structure between CO<sub>2</sub> and global temperature

Authors: Adolf Stips<sup>1\*</sup>, Diego Macias<sup>1</sup>, Clare Coughlan<sup>1</sup>, Elisa Garcia-Gorriz<sup>1</sup>, X. San Liang<sup>2</sup>

**Table SI-1**

Causality between CO<sub>2</sub> and GMTA time series (1850-2012) based on different causality measures. We find significant information flow from CO<sub>2</sub> to GMTA, significant bi-directional causation using Granger causality and significant causation directed from GMTA to CO<sub>2</sub> using CCM method. This reveals quite clearly the problem of not detecting *nil causality* with the other methods.

	Causality measures: CO <sub>2</sub> – HADCRUT4			
	CO <sub>2</sub> → GMTA		GMTA → CO <sub>2</sub>	
	[nat/ut]	95%	[nat/ut]	95%
Information flow	<b>0.348</b>	<b>±0.112</b>	-0.006	±0.003
	<b>F</b>	<b>p</b>	<b>F</b>	<b>p</b>
Granger	<b>36.23</b>	<b>1.171e-08</b>	<b>10.81</b>	<b>1.244e-03</b>
CCM		0.08		<b>0</b>

**Table SI-2**

Causality between detrended CO<sub>2</sub> and detrended GMTA time series (1850-2012) based on different causality measures. We find significant information flow from CO<sub>2</sub> to GMTA, also significant directional causation using Granger causality and significant causation directed from GMTA to CO<sub>2</sub> using CCM method. This reveals quite clearly the problem of not detecting *nil causality* with CCM method.

Detrended data	Causality measures: CO <sub>2</sub> – HADCRUT4			
	CO <sub>2</sub> → GMTA		GMTA → CO <sub>2</sub>	
	[nat/ut]	95%	[nat/ut]	95%
Information flow	<b>0.162</b>	<b>±0.077</b>	-0.006	±0.007
	F	p	F	p
Granger	<b>16.403</b>	<b>7.98e-05</b>	2.462	0.119
CCM		0.27		<b>0.01</b>

**Table SI-3**

Calculated F-statistics and p-value (significant when  $<0.05$ ) for Granger causality between different forcings and HADCRUT4 global temperature data. Bold values are significant at the 95% level (p-value  $< 0.05$ ). Several significant reverse flows reveal quite clearly the problem of not detecting *nil causality* using Granger causality. Further we provide the name of the forcing components as used by Meinshausen et al. 2011 and as used in the carbon cycle model MAGICC6.

**Fig. SI-1**

Comparison between cumulative Liang causality (information flow) and Granger causality calculated between total anthropogenic forcing and GMTA time series. In the case of Granger causality the F-statistics is plotted and scaled to the same range as the information flow. The thick lines at the bottom of the figure depict time periods with significant causality at the 95% level. In the case of existing causality Granger causality might therefore provide similar results as with the information flow.

The effect of increasing time-series length on the information analysis was tested using artificially created dependent time-series X and Y (where X cause Y by a linear combination). The information analysis results (Fig. SI-2) do reveal a rapid convergence of the information flow ( $\sim 1$ ) since the beginning of the cumulative analysis. This demonstrates that the length of the considered time-series did not fundamentally influence the information flow calculations, which are, nonetheless, expressed as a function of the time-step as described above.

**Fig. SI-2**

Liang cumulative information flow for a time series X1 (length 200 years) that is linearly causing X2. White noise is added to both time series. Black squares indicate significant information flow. Immediately when beginning the first calculation the information flow is significant and stays about 1 [nat/year].

**Fig. SI-3**

Liang cumulative information flow for a time series X1 (length 200) that is linearly causing X2. White noise is added to both time series. However the first 100 elements are replaced by white noise only, so that the signal starts now at element 101. The white noise does not produce any significant information flow. Shortly after the signal starts the information flow is significant and is initially increasing fast before approaching a seemingly stationary behavior. It can be noted that already after a period of only 5 causal related years the calculated information flow is significant, despite the preceding 100 years of white noise.
